Title: Method for operating a chemical and/or physical process by means of a hierarchical fluid injection system

The invention relates to a method for operating a chemical and/or physical process, e.g. a fluid bed reaction, and especially deals with the injection of fluids, such as gases, liquids and/or suspensions in a controlled typically uniform way. More in detail, the chemical and/or physical processes 5 are carried out within a vessel containing a fluid or fluidized medium, which medium can be a gas and/or a liquid, optionally in combination with solid particles. The fluids are injected using an injection device consisting of tubes or channels that are connected in a hierarchical fashion so that the fluid entering a first channel is divided into channels of the same or different 10 diameter and length, each or some of which are further divided into channels of the same or different diameter and length, and so on. The injection system can also comprise combinations of such tree-like or fractal-like elements, embedded in a plane (two-dimensional) or in space (three-dimensional).

Multiphase reactors or multiphase contacting devices, are commonly 15 applied in process industry. In such processes two or more fluids have to be brought into contact with each other to efficiently transfer one or more components from one phase into another phase, where the reaction or contacting process occurs. This is in particular so for transport limited processes, of which there are many in industrial practice.

20 The invention can be used for gas/solid fluidized bed, gas/liquid and other processes. A typical application is the reduction and uniformization or otherwise control of bubble sizes to optimize the operation of fluidized bed, slurry and gas/liquid reactors. The embodiments of the present invention will depend upon the nature of the fluids and the application.

25 An important example is a fluidized bed reactor, where gas is injected through a distributor plate in the bottom of a vessel to fluidize a bed of solid particles that are to react with the gas or catalyze a chemical reaction between gas molecules. Gas bubbles grow from the bottom to the top of the bed as a result of the pressure difference over the bed, simply because of the 30 thermodynamics. The movement of the fluidized solid particles and the bubbles is turbulent, chaotic, and strongly dependent on the operating conditions.

Fluidized bed reactors are of considerable economic importance. An example of a large scale process that is preferably carried out as a fluidized bed process is the Fischer-Tropsch synthesis of liquid fuel from synthesis gas, which can be obtained by steam-oxygen gasification of coal or other hydrocarbons. This process involves the contacting of the gas stream with solid catalyst particles to produce the fuel:

Another important example in which similar problems occur is a gas/liquid process carried out in a bubble column or stirred tank reactor. The gas moves up from a distributor through a reactor vessel. The movement of the bubbles is again extremely complex. Typically, the shape and size of the bubbles cannot be or is hardly controlled and bubbles coalesce and grow as a result of the pressure difference between the top and the bottom of the reactor. A mixing device and fixed internals may be installed inside the vessel to improve the mixing by increasing the turbulence in the bed. Similar complex hydrodynamics exist for other processes in which several fluids or fluidized media are contacted to react or catalyze reactions.

To optimize the reaction process, the interfacial area between the fluid phases should be maximized or otherwise controlled. With the presently used reactor systems or physical contacting devices, this forms a serious problem, especially because the hydrodynamics, as described above, are so complex.

Mixers can be used to increase turbulence and contacting, but they consume costly energy. In other cases, such as gas/solid fluidized beds, mixers may not be used. In addition, mechanical problems arise when mixing devices are employed.

Homogenization, i.e., achieving equal conditions at every point in the reactor vessel, is difficult to achieve. Imposing particular concentration or partial pressure profiles is even more difficult or for most reaction systems impossible. The existence of dead volumes, where no or much less reaction occurs, because of decreased local flow, is often inevitable.

Another problem in current realizations of such multiphase reactors and other processes involving several fluids or fluidized media that need to be contacted is 'scaling up' of these devices. A process is usually first investigated

on a smaller scale, e.g. on lab scale, bench-scale or pilot scale, and then needs to be scaled up to the typically much larger industrial scale. Rules to scale up multiphase processes are typically empirical or at least semi-empirical and the errors are very large, because the processes are influenced by the

5 hydrodynamics. With the present methods, it is a serious challenge to maintain similar hydrodynamics during scale up from the small to the large scale. In most cases, this is even impossible.

Whenever in this specification and the appended claims reference is made to a 'vessel' it is to be understood that this refers to a container for fluids and optionally particles, in which optionally provisions are made to feed additional fluids and/or particles, and optionally provisions are made to remove fluids and/or particles. Preferably such a vessel is operated in a continuous or semi-batch process. The examples of processes mentioned above, are all carried out in vessels.

15 In the prior art several publications are known which address at least part of the above mentioned problems.

In U.S. Patent 4,537,217 a fluid distributor is disclosed having a distribution surface with a plurality of uniformly spaced distribution openings, which is particularly suitable for application in chromatography.

20 U.S. Patent 4,999,102 discloses a liquid distributor for distributing and/or collecting a liquid in large scale industrial processes, such as absorbers or desorbers.

U.S. Patent 5,354,460 discloses a fluid transfer system for obtaining uniform liquid distribution in industrial scale fluid transfer systems which 25 accommodate plug flow operations.

All of these publications relate to the uniform distribution or collection of a liquid by means of a planar device which stretches out horizontally. The devices described in these prior art documents are placed at the inlet or outlet of the corresponding unit-operation. Each point in the plane 30 would be reached, were the constructions described in these documents continued ad infinitum. At the outlets, the liquid pours out or is collected in a uniform way; typical applications are in chromatography.

Finally, Kearney (in: Fractals in Engineering, INRIA Proceedings, June 25-27, 1997, Arcachon, France) describes a three-dimensional mixing 35 unit, which consists of a recursive structure of pipes. This structure is suitable for emulating turbulence using laminar flows.

The structures disclosed in above mentioned patents are not suitable or optimal for controlling three-dimensionally local parameters such as pressure and flowrates for improved operation of chemical and/or physical processes in vessels, such as described hereinbefore. Moreover, none of these 5 documents is directed to multiphase processes, nor to scaling up such processes.

It has now been found that the above mentioned problems can be solved by introducing a fluid in said vessels by means of a hierarchical network of channels comprising parent and child generations of channel 10 formations, wherein substantially each channel in a parent generation is divided into N channels of the child generation, which network terminates in channel exits, such that said fluid is discharged from the channel exits substantially uniformly throughout the vessel volume.

By discharging the introduced fluid substantially uniformly 15 throughout the vessel volume, as is enabled by the network structure, it was found that the operation of the processes which were carried out in said vessels is improved considerably. The introduction of fluids through said network results in equal pressures at all outlets of the tree. When the fluid is a gas, 20 this leads to equal or otherwise controlled bubble sizes, distributed as directed by the position of the outlets inside the vessel. A substantial uniform discharge of the fluid is intended to refer to a situation in which the discharge conditions with respect to local pressure and/or fluid velocity at substantially all channel 25 exits is substantially the same.

The network of channels according to the invention is a recursive 30 structure, in which different generations of channel formations can be distinguished. When reference is made to a 'parent generation', a formation of channels having a certain geometry and a certain size is meant. Each formation can comprise one or more channels or groups of channels, which 35 channels are essentially of the same size or which groups of channels comprise channels of the same size in essentially the same orientation, and the geometry of which channels or groups of channels are the same and these channels or groups of channels are arranged in any mutual order within each formation, although usually the arrangement within each formation will be regular or otherwise well defined. A 'child generation' is intended to be a formation of channels, which channels are substantially similar in geometry to

the channels of the corresponding parent generation from which it is branching, and either of the same or smaller size.

Substantially each channel of a parent generation branches into N channels which are members of its child generation. The value of N will

5 depend on the process and what is practically achievable. According to the present invention, N is at least 2. The upper limit of N will be strongly determined by what is practically achievable, typically N will be smaller than about 8, preferably smaller than 6.

One of the surprising features of the present invention is that when 10 N is not the same for all channels, for example when one of the channels is clogged, resulting in stopped flow of all the channels belonging to its child generation or generations, this does not necessarily adversely influence the process. Therefore, according to the invention, some variation in the value of N throughout the network is acceptable, depending on the application and the 15 generation of channels it refers to, as long as substantially each channel branches into N channel. This means that according to the present invention a small fraction of the channels may branch in less than N channels, or even into no channels at all, without departing from the general concept of the present invention.

20 The injection devices which are used in the present invention comprise successive generations of channels, the first generation of channels being fed by a formation which is not necessarily a hierachic structure. The last generation (bearing the highest number) comprises the channels that discharge in the vessel.

25 The number of generations will depend on the type of process. For a given application the person skilled in the art will be able to establish the required number of generations to construct a network that fills the volume of the vessel in an adequate manner. Usually, for most practical applications the number of generations does not exceed about 10.

30 Channels are defined here as structures capable of transporting fluids, such as pipes, hoses or any duct.

35 In a preferred embodiment of a method according to the present invention, the network is a self-affine network of channels, i.e. a network wherein for several generations, the ratio of successive lengths is constant for channels of different generations running in the same direction. The ratio of successive diameters in a self-affine network is also constant, but the length

and diameter ratios need not be the same. In this preferred embodiment each of the channels in the parent generation have a diameter d_j and length l_j and each of the channels in the child generation have a diameter d_{j+1} and length l_{j+1} , wherein the ratios d_j/d_{j+1} and/or the ratios l_j/l_{j+1} are substantially constant for channels of successive generations running in parallel direction. In this embodiment said network can also be a self-similar network which is a type of said self-affine network wherein the ratios d_j/d_{j+1} and l_j/l_{j+1} are substantially constant for channels of successive generations independent of their direction.

By employing a self-affine network, optimal use can be made of the available volume of the vessel, which often has dimensions that are not equal in all directions. A self-similar network would be especially useful in processes which are carried out in vessels which have more or less equal dimensions in all directions.

The networks of channels in the method of the present invention can also be combined, viz. it is possible to construct networks comprising sub-networks that are self-affine or self-similar without departing from the general concept of the present invention. Such a combined network is therefore not necessarily self-affine or self-similar, but as long as it comprises elements that are at least substantially self-affine or self-similar, the effects of the present invention can be obtained.

Although self-affine and self-similar structures are preferred embodiments of the present invention, and although the requirement of self-affinity or self-similarity results in a structure wherein all exits have similar dimensions, deviations from this definition can exist in networks according to the invention, without departing from the general concept of the present invention. Such 'non-perfect' structures can still provide the desired effect described herein. In fact it is sometimes desirable to introduce such deviations from the strict self-affine and self-similar structures on purpose, for example in order to further minimize the influence of gradients, such as pressure and/or concentration gradients, which often inevitably exist in vessels in which the networks according to the present invention are applied. By carefully varying the length and diameter of the channels of the network, in particular the diameter of the channels near the exits, gradients in factors such as local bubble size, pressure drop and/or hydraulic path length can be imposed and consequently an even better control of the process is possible.

This feature which enables enhanced controlling and becomes possible with the hierarchical fluid injection system according to the present invention will be referred to as to 'otherwise control' the processes wherein it is applied. It was found that the variations in exit diameters could be introduced 5 quite simply by plugging the exits of the network with different plugs having holes of varying diameter.

Strictly speaking, self-affine or self-similar embodiments of the present invention require that each successive generation comprises channels that are in the same direction as the corresponding channels in the parent 10 generation, or that the child channels are regularly rotated with respect to their corresponding parent channels, the rotation being the same for each successive generation. It is to be understood that small deviations from this strict requirement need not influence the applicability of the channel network. In general, the influence of such deviations from this strict self-affinity or self- 15 similarity with respect to orientation, becomes less in higher generations, i.e. in generations closer to the exits. This can be convenient in practical applications, since it allows flexibility in applying the network injection devices according to the present invention.

It has also been found that especially suitable networks for 20 application in a method according to the present invention can be obtained when such networks are constructed such that the ratios of diameters and/or lengths of channels in successive generations of said network are related to N by

25 $N = (d_j/d_{j+1})^\Delta$, and/or

$$N = (l_j/l_{j+1})^D,$$

wherein Δ and D represent an integer or a real positive number.

It has been found that the control of flow or diffusion through the channels is especially effective when the above mentioned relations are 30 fulfilled. The method according to the invention can be easily optimized by using these relations, as will be explained hereafter.

Preferably the value of D is between 2 and 3. In this case the resulting network will make use of the volume it extends in, while at the same time avoiding interference with the fluid inside the vessel which may be in

motion and leaving enough space for the multiphase process that takes place inside the vessel.

Preferred processes in which any of the above mentioned networks can be successfully applied, are fluidized bed processes, slurry processes, 5 gas/liquid bubble column processes, aeration processes and liquid/liquid mixer or reaction processes, since all of these processes suffer from the problems set out in the above and can therefore benefit from the method of the present invention.

For instance aeration processes are carried out in an aerator which 10 contains an aqueous liquid phase in which a solid phase biomass is present. The biomass must be kept in suspension and a certain degree of turbulence must be maintained. Oxygen is supplied by bubbling air through the reactor. By applying a network as set out in the above, optimal mixing can be obtained, even without employing moving parts, and at the same time the formation of 15 too large air bubbles is avoided.

Another surprising advantage of the present invention is the ease of scale up of processes. A method for scaling up according to the present 20 invention comprises building a small scale vessel in which vessel a fluid is introduced through a hierarchical network of channels which can be any network as described in the above, such that said fluid is discharged from the channel exits substantially uniformly throughout the vessel volume and determining optimal geometry and optimal values for the parameters N, Δ and 25 D, and subsequently building a large scale vessel in which said geometry and parameters are substantially the same as in the small scale vessel. According to this method N, D and Δ are kept constant but the number of generations as well as the absolute respective lengths and/or diameters may differ to suit the demand of the large scale application.

The network according to the invention could be modified to further 30 control the processes wherein it is applied, by having at least one material present near the exits of said network and/or said material is present as a coating on at least part of the inner surface of said network, which material is capable of chemical and/or physical interactions with fluids. Such materials could e.g. be a catalyst, an ion exchanger and/or an adsorbent. Examples are zeolites or ion exchange resins.

35 As mentioned in the above, further control can also be obtained by providing to any of the above mentioned networks means for obtaining a

gradient in the dimensions of the respective exits. It was found that the variations in exit diameters could be introduced quite simply by plugging the exits of the network with different plugs having holes of varying diameter. When applied in a bubble column for instance, such an injection system could

5 provide a means to further control the uniformity of the process by imposing the bubble sizes. When applied in fluidized beds, a gradient in the exit diameters of the channels of the hierarchic channel network system could provide a means to further control the uniformity of the process, since bubbles introduced near the bottom could reach diameters that, in the absence of any

10 intrinsic pressure gradient resulting from the fluid column, would be substantially larger than the bubbles that are introduced near the top of the column.

The method according to the present invention enables optimized production using the above mentioned processes in combination with

15 hierarchic network channels.

The networks of the present invention can be constructed easily by a variety of methods. For example, T- or Y-shaped elements can be connected easily by all kinds of means, such as gluing, soldering, welding, clamping, etc. Such networks can be easily extended by simply adding additional elements.

20 Suitable materials for constructing the networks according to the present invention are all materials that are essentially inert to the reaction conditions, e.g. stainless steel, or other metal, glass, quartz glass, etc.

It is also possible to use a bundle of flexible channels, which are subsequently formed to the desired shape, viz. having their exits at the desired

25 location in space. In such a network of all similar channels, $\Delta = 2$.

It should be mentioned that the actual structure of the hierarchical network is quite different for different processes. A channel may split into N channels, of which the lengths and diameters are the same or, usually, smaller than that of the parent channel. Each of these channels splits in the same or

30 different way. A typical, yet not the only possible, division is such that, within a certain range of scales, a self-similar or self-affine network results: for several generations, the ratio of successive lengths is constant. The ratio of successive diameters is also constant, but the length and diameter ratios need not be the same. The ratios of diameters will control the flow or diffusion

35 through the channels. Assume, e.g., a division of each channel of diameter d_j into N new channels of diameters d_{j+1} . The ratio d_{j+1}/d_j is typically maintained

constant over several generations. Then, the diameter exponent Δ can be defined as follows:

$$(d_j)^\Delta = N(d_{j+1})^\Delta \text{ or } N = (d_j/d_{j+1})^\Delta$$

5 If the diameter exponent $\Delta=2$, the flow rates are the same through successive constructions, because the flow cross-section is the same throughout: when all the small branches of a certain generation are taken together then the sum of cross-sectional areas of all channels belonging to a 10 certain generation is the same as the cross-sectional area of the preceding generation.

When Δ is 3, however, a complete volume is reached, but the flow is slowed down through the network. Δ may take intermediate values with corresponding effect. If all channel diameters are the same, Δ becomes 15 infinitely large.

15 Optimal values of Δ depend on the type of process. A person skilled in the art will be able to determine, optionally aided by routine experiments optimal values for each process.

20 The set of outlet points of all the channels is, in the limit for an infinite number of generations, a fractal, with a fractal dimension D defined by the self-similar branching. If a finite subset, and possibly all points, are reached within the (embedding) space in which the network lies, then the 25 fractal dimension D equals the embedding dimension, i.e., 3 for a volume and 2 for a structure within a plane. For a 'network' consisting of a single channel, D would become zero because there is only one outlet. By controlling the branching ratio N and the ratio of successive lengths of the elements or channels that are combined in the network, l_{j+1}/l_j , the fractal dimension D , defined by:

$$(l_j)^D = N(l_{j+1})^D \text{ or } N = (l_j/l_{j+1})^D$$

30 may be modified to take fractional values in between zero and the embedding dimension (2 or 3). In this way, through D and Δ and the relative orientation of successive units in the hierarchy, a variety of structures can be 35 formed.

Advantages such as robustness, trivial scalability and/or ease of construction of such hierarchical designs for technical applications as described above have not been perceived until now. The above cited prior art relates to the uniform distribution or collection of a liquid by means of a planar 5 (two-dimensional) device in which all the channels have the same lengths or form a hierarchical network of a well-defined, specific structure disclosed in the patent. Each point in the plane would be reached, were the constructions described in the patent continued ad infinitum, hence $D=2$. At the outlets, the liquid pours out or is collected in a uniform way; typical applications are in 10 chromatography.

The prior art structures are not suitable or optimal for the present applications to which the present invention relates, for which other D and Δ may and will usually be better, and combinations of hierarchical structures can be employed. Also, the devices described in the present patent are used 15 inside a three-dimensional or possibly quasi-two-dimensional vessel (i.e., a vessel where one of the dimensions is much less than the other two), and not on top or below it. Applications are typically in the field of multiphase reactor engineering, although not limited to the latter. If $D=2$, every point in the plane will be reached, yet the complete available surface area is filled. This may be 20 optimal for a distributor, yet not for an injector inside a vessel, where a large free volume needs to remain available for the reactions, absorption or other physico-chemical processes.

Another device according to the present invention can be used to distribute a fluid in a controlled and typically uniform way, so that the 25 pressure drop from the inlet or inlets to the multitude of outlets is the same or otherwise controlled through the geometry of the structure. This device has the following design. A first channel, through which a fluid enters the device, splits in N_1 channels of the same or lower diameter and length, each of which again splits in N_2 channels of the same or lower diameter and length, and so 30 on, until a smallest scale. Several such hierarchical constructions may be linked into a larger spatial structure: in this case, one main inlet pipe typically branches out into N_0 hierarchical fluid injection structures. The complete injection device is placed inside a vessel; depending on its size, if necessary, it is attached to the walls of the vessel.

35 Although the disclosed family of structures to which the claims relate is more general, (fractal) self-similar and self-affine designs are

particularly attractive because of the ease of scaling up such structures. A self-similar structure is one where parts of the structure are rescaled copies of the whole; this is in principle only possible for true fractals with an infinite scaling range – the self-similarity is therefore interpreted to be valid only down to a 5 smallest scale, the inner cutoff. For a self-affine structure, the similarity ratios of elements in different directions is different; they appear like stretched self-similar structures. Self-affine structures are also scalable and may be attractive alternatives to self-similar structures for vessels that have different dimensions in different directions (e.g., a cylinder with a diameter different 10 from its height). Easy scalability and facilitated construction in a wide range of sizes are two results of this hierarchical structure. It suffices to add additional generations in the hierarchical cascade(s) to make a larger structure, without changing the flow pattern. These are some of the features 15 that make the networks of channels according to the present design attractive.

15 The largest and smallest sizes of the channels in the hierarchical fluid injection system depend on the particular application and on the size of the vessel. The fluid outlets are usually at the last stage. They may have a special process-dependent shape or structure that is different from all other channels and contain a porous plug, non-catalytic or catalytic material, 20 depending on the application.

25 The branching ratios of the hierarchical fluid injection system, N_1 , N_2 , etc. need in principle not be equal to each other, but in a self-similar or self-affine scalable structure (the preferred embodiment for many applications), they are all equal and denoted by N .

Another interesting possibility is that $N^I = N_1 = N_3 = N_5 = \dots$ and $N^{II} = N_2 = N_4 = N_6 = \dots$, so that $N = N^I \times N^{II} = \text{constant}$. Obvious generalizations hereof are also possible.

30 Two or more successive branchings may actually be considered as belonging to the same (double) generation, which makes the final design also self-similar or self-affine, apart from the inlet channel or 'trunk' of the tree.

35 By the definition given above, the ratio of the sizes of successive elements is constant and the same in all directions for a self-similar design, while in a self-affine design, the generation independent ratio is different in different directions (e.g., the vertical and the horizontal directions). Again, the trunk, connecting different trees, is the natural exception. The diameter exponent Δ and the fractal (similarity) dimension D , defined earlier, are two

characteristic numbers for the hierarchical construction, as they are directly related to the ratio of successive channel diameters and lengths respectively.

Their values are very important to achieve a uniform or otherwise controlled injection of fluid into the vessel containing the second fluid. They
5 are strongly dependent on the application. In general, high values of Δ are suitable for bulkier structures that fill more space, but the resistance to flow through the structure is low. High values of D may also typically yield bulkier structures, although the bulkiness may be compensated by a lower value of Δ . When D is higher, the inlets reach a larger fraction of the vessel, yet less space
10 is available for the fluid inside the vessel, which may not be desirable. The optimum of D , Δ , the number of generations, and the branching ratios, is clearly determined by the problem at hand, viz. the process to be operated, yet the global geometrical properties of the hierarchical structure claimed through this patent are similar and described as above: all these structures belong to
15 the same family.

The facile control over the distribution of the fluid injection point locations and of the constant or otherwise controlled injection flow rates of the injected fluid, means that a physico-chemical process inside the vessel can be geometrically controlled in a unique way. Homogenization or uniformization of
20 flow is usually attempted by mixing, which involves mechanical devices that consume energy and are more complex to build and maintain than the present invention. Although a hierarchical fluid injector may be used as a fluid injecting mixer, it does in its typical operation mode not involve moving parts, presenting another advantage over conventional designs. Another advantage is
25 that a hierarchical unit can also be very robust against clogging, which is especially important when solids are involved in the process.

Furthermore, the hierarchical fluid injection system of the invention can significantly increase the performance of a chemical reaction carried out in a multiphase reactor.

30

Brief description of the drawings

It is to be understood that the shown embodiments only serve as good examples to carry out the invention in particular situations, yet that the structures to which this application relates are much more general, as
35 described above.

Figure 1 shows a two-dimensional projection of a quasi-two-dimensional fluid injection device that can be used to inject secondary gas in a gas/solid fluidized bed. When the device is put inside a bed of solid particles, fluidized at minimum fluidization by a distributor under the bed, fluidization is uniform and the bubbles are of a constant and controlled size, under a wide range of operating conditions.

5 The shaded areas indicate channels belonging to the first generation (1) and channels belonging to the third generation (3).

10 Figure 2 shows a two-dimensional projection (looking top down) of a three-dimensional fluid injection device that can be used to inject secondary gas in a gas/solid fluidized bed or in a gas/liquid reactor.

15 Figure 3 shows the same fluid injection device as in Figure 2 but under a different angle.

15 The invention will now be illustrated by the following examples, which are added for illustration only and are not intended to limit the scope of the invention in any sense.

Example 1

20 A device as depicted in Figure 1 was assembled out of Plexiglas tubes to observe and illustrate the capabilities of a hierarchical fluid injection system. It consisted of a central tube, which divided into 2 tubes that further divided into 2 tubes, all in the same plane so as to form an H-shape connected to the central tube. The horizontal bar of the H was as long as each of the 25 vertical bars. Four hollow H-shapes, twice as small as the just described H, were connected to the open extremities of the latter H. All tubes in this example had the same diameter, were hollow and contained a hole in the middle to connect to a tube of the previous generation. The connections were 30 made using glue and such that there were no leaks. The width of the injector is 17 cm:

35 The hierarchical construction was submerged in a rectangular bed, made out of Plexiglas, with a thickness of 1.5 cm and a width of 20 cm, containing solid particles (sand particles with a mean size of 200 μm and a density of 2600 kg/m^3). The bed was fluidized at minimum fluidization (the particles were just fluidized as an emulsion phase) using an air stream

through a distributor below the bed, i.e., the common way of operating a fluidized bed. Secondary air was injected through the hierarchical fluid injection system. Under a wide range of conditions (tested until 6 times the minimum fluidization rate), the bed was fluidized with small uniformly distributed bubbles. Air distribution through the lower distributor only, gave rise to a swarm of very large and smaller bubbles, which coalesced. Additional air injection through the described injection device changed the movement from highly chaotic to nicely controlled and uniform, as desired. Even after partial clogging of some tubes by solid particles, the unit functioned in an excellent way, demonstrating its robustness.

Example 2

A three-dimensional hierarchical fluid injection device according to Figures 2 and 3 was assembled from tubes of the same materials as in the previous example, yet they did not have the same size. A vertical central tube divides into 6 tubes, branching out horizontally with their endpoints on a regular hexagon. From the endpoint of each tube descends another tube. In the present example, each of the latter tubes branched into 3 tubes in the same plane. This 'generating unit' repeated through a self-similar cascade. From the endpoints of each of these tubes, said generating unit was connected vertically up and vertically down. The vertical tubes were connected. The 3 horizontal tubes of the upper generating unit were oriented in a direction directly opposed to that of the tubes of the lower unit, and the tubes are parallel to the tubes forming the hexagon mentioned above. This procedure was continued in a recursive way. Fluid could flow from the inlet through the structure to and through each of the extremities of the smallest tubes. The diameter of the network was 35 cm.

Diameter and length ratios of the tubes are variable and depend on the particular application. For a gas/liquid process, it was found that a low value of the diameter exponent Δ is favorable, while for a gas/solid process a higher value with a few generations is best. In the shown self-similar design, by means of example, the fractal dimension was $D = \log 6 / \log 2 \approx 2.58$. In the described implementation, a projection of the setup will give a hexagonal grid, as shown in the figure: the dimension of this projection is 2, which means that bubbles of a gas flowing through the structure may rise through the vessel and

reach a maximum volume, even while the total structure does not occupy too much space, as indicated by the low value of the fractal dimension, substantially lower than 3.

5 Example 3

A structure similar to Figure 1, about 10 cm in size, was built out of hollow metal channels with a diameter down to 100 μm and submerged horizontally in a vessel filled with water. The diameter exponent Δ of the 10 structure was 2 and the structure consisted of 3 generations. It was observed that when air was blown through the horizontal structure, bubbles of the same size rose from the 64 exits. Moreover, even at relatively high gas rates, the bubbles rose in nice parallel streets without visible coalescence either 15 horizontally or vertically. Such uniform behavior is highly desirable for gas/liquid absorption, aeration and other reactor processes, because it makes the mass transfer of components between the gas and liquid phase very efficient.

Example 4

20 The experiment of Example 3 was repeated, but now a vessel filled with glycerol was used instead. Similar results were obtained; bubbles of the same size rose from the 64 exits when air was blown through the horizontal structure. Again the bubbles rose in nice parallel streets without visible 25 coalescence either horizontally or vertically.

Example 5

A device like the one depicted in Figure 1 and twice as large as the 30 device in Example 1 (width of 34 cm), made out of the same Plexiglas tubes, but with 64 outlets instead of 16, was assembled to observe and illustrate the scale-up capabilities of a hierarchical fluid injection system. It consisted of a central tube, which divided into 2 tubes that further divided into 2 tubes, all in the same plane so as to form an H-shape connected to the central tube. The 35 horizontal bar of the H was as long as each of the vertical bars. Four hollow H-shapes, twice as small as the just described H, were connected to the open

extremities of the latter H. Again, four hollow H-shapes, twice as small as the just described H, were connected to the open extremities of each H obtained in the previous step. This led to a fluid injection system with 64 outlets. The construction was such that the size of the smallest tubes was the same as the 5 one in Example 1. All tubes in this example had the same diameter, were hollow and contained a hole in the middle to connect to a tube of the previous generation. The connections were made using glue and such that there were no leaks.

A similar experiment as in Example 1 was conducted. The 10 hierarchical construction was submerged in a larger fluidized bed of the same solid particles; the width of the bed was now doubled to 40 cm. The bed was again fluidized at or slightly above minimum fluidization (the particles were just fluidized as an emulsion phase) using an air stream through a distributor below the bed, i.e., the common way of operating a fluidized bed. Secondary air 15 was injected through the hierarchical fluid injection system.

Under a wide range of conditions (tested until 6 times the minimum fluidization rate), the bed was fluidized with small uniformly distributed bubbles. Only very close to the upper surface were larger bubbles observed. Within the bed, the bubble distribution was much more uniform than without 20 the injection device and similar to the one observed with the smaller injection device in Example 1.

As a reference, gas flow through the injector was shut off and air distribution through the lower distributor only was studied. This gave rise to a swarm of very large and smaller bubbles, which coalesced.

25 Additional air injection through the described injection device changed the movement from highly chaotic to nicely controlled and uniform, as desired.

These experiments demonstrate the size-independent capability of the fluid injection system of the invention to make the bubble distribution 30 more uniform, the bubbles much smaller, and the behavior similar in small and large setups, without having to employ moving parts.

Example 6

The hierarchical fluid injection system of the invention can significantly increase the performance of a chemical reaction carried out in a multiphase model reactor, such as a fluidized bed reactor.

5 The Pt catalyzed oxidation of CO on a 0.5% Pt/Al₂O₃ catalyst from Heraeus, for which the kinetics were known from fixed bed experiments, was carried out in a 5 cm diameter fluidized bed. The conversion was determined in the fluidized bed under normal bubbling conditions, i.e., without the fluid injection system, at 180 °C and with 560 µm catalyst particles.

10 The conversion is also determined using uniform operation conditions achieved with a hierarchical fluid injection system of the invention.

15 From these conversions it follows that use of the fluid injection system increases the conversion from 28% to 37% at 4 times the minimum fluidization conditions, which is a 30 percent increase. This comparison indicates the potential of the fluid injection system.

Claims

1. Method for operating a chemical and/or physical process in a vessel containing a liquid, a gas and/or solid particles, in which vessel a fluid is introduced through a hierarchical network of channels comprising parent and child generations of channel formations, wherein substantially each channel in a parent generation is divided into N channels of the child generation, whereby each of said child generations may in turn be a parent generation for a successive child generation, which network terminates in channel exits, such that said fluid is discharged from the channel exits substantially uniformly throughout the vessel volume.
- 10 2. Method according to claim 1 in which said network is a self-affine network of channels, wherein each of the channels in the parent generation has a diameter d_j and length l_j and each of the channels in the child generation has a diameter d_{j+1} and length l_{j+1} , wherein the ratios d_j/d_{j+1} and/or the ratios l_j/l_{j+1} are substantially constant for channels of successive generations running in parallel direction or in which method said network is a self-similar network which is a type of said self-affine network wherein the ratios d_j/d_{j+1} and l_j/l_{j+1} are substantially constant for channels of successive generations independent of their direction.
- 20 3. Method according to claim 2 wherein the ratios of diameters and/or lengths of channels in successive generations of said network are related to N by

$$N = (d_j/d_{j+1})^\Delta, \text{ and/or}$$

$$N = (l_j/l_{j+1})^D,$$

wherein Δ and D represent an integer or a real positive number.

- 25 4. Method according to claim 3 wherein D is between 2 and 3.
5. Method according to claim 1, in which said chemical and/or physical process is selected from a group consisting of a fluidized bed process, a slurry

process, an absorption process, a gas/liquid bubble column process, an aeration process and a liquid/liquid mixer or reaction process.

6. Method for scaling up chemical and/or physical processes which processes are carried out in a vessel comprising the steps of building a small 5 scale vessel in which vessel a fluid is introduced through a hierarchical network of channels comprising parent and child generations of channel formations, wherein substantially each channel in a parent generation is divided into about N channels of the child generation, which network terminates in channel exits, such that said fluid is discharged from the 10 channel exits substantially uniformly throughout the vessel volume and determining optimal geometry and optimal values for the parameters N, Δ and D, and subsequently building a large scale vessel in which said geometry and parameters are substantially the same as in the small scale vessel.

7. Vessel containing a hierarchical network of channels, said network 15 comprising parent and child generations of channel formations, wherein substantially each channel in a parent generation is divided into N channels of the child generation, whereby each of said child generations may in turn be a parent generation for a successive child generation, which network terminates in channel exits, wherein said network is a self-affine network of channels, 20 wherein each of the channels in the parent generation have a diameter d_j and length l_j and each of the channels in the child generation have a diameter d_{j+1} and length l_{j+1} , wherein the ratios d_j/d_{j+1} and/or the ratios l_j/l_{j+1} are substantially constant for channels of successive generations running in parallel direction or in which vessel said network is a self-similar network 25 which is a type of said self-affine network wherein the ratios d_j/d_{j+1} and l_j/l_{j+1} are substantially constant for channels of successive generations independent of their direction.

8. Vessel according to claim 7 wherein the ratios of diameters and/or 30 lengths of channels in successive generations of said network are related to N by

$$N = (d_j/d_{j+1})^\Delta, \text{ and/or}$$

$$N = (l_j/l_{j+1})^D,$$

wherein Δ and D represent an integer or a real positive number.

9. Vessel according to claim 8 wherein D is between 2 and 3.
10. Hierarchical network of channels comprising parent and child generations of channel formations, wherein substantially each channel in a parent generation is divided into N channels of the child generation, whereby each of said child generations may in turn be a parent generation for a successive child generation, which network terminates in channel exits, which said network is a self-affine network of channels, wherein each of the channels in the parent generation have a diameter d_j and length l_j and each of the channels in the child generation have a diameter d_{j+1} and length l_{j+1} , wherein the ratios d_j/d_{j+1} and/or the ratios l_j/l_{j+1} are substantially constant for channels of successive generations running in parallel direction or which network is a self-similar network which is a type of said self-affine network wherein the ratios d_j/d_{j+1} and l_j/l_{j+1} are substantially constant for channels of successive generations independent of their direction and wherein the ratios of diameters and/or lengths of channels in successive generations of said network are related to N by

$$N = (d_j/d_{j+1})^\Delta, \text{ and/or}$$

$$N = (l_j/l_{j+1})^D,$$

- 20 wherein Δ and D represent an integer or a real positive number.

11. Network according to claim 10 wherein D is between 2 and 3.
12. Network according to claim 10 wherein at least one material is present near the exits of said network and/or said material is present as a coating on at least part of the inner surface of said network, which material is capable of chemical and/or physical interactions with fluids.
- 25 13. Network according to claim 10 which is provided with means for obtaining a gradient in the dimensions of the respective exits.
